

Executive summary report

TikTok claim status classification model

Overview

The TikTok data team seeks to develop a machine learning model to assist in the classification of videos as either claims or opinions. Previous investigation into the available data revealed that video engagement levels were highly indicative of claim status. The team is confident that the resulting model will meet all performance requirements.

Problem

TikTok videos receive a large number of user reports for many different reasons. Not all reported videos can undergo review by a human moderator. Videos that make claims (as opposed to opinions) are much more likely to contain content that violates the platform’s terms of service. TikTok seeks a way to identify videos that make claims to prioritize them for review.

Solution

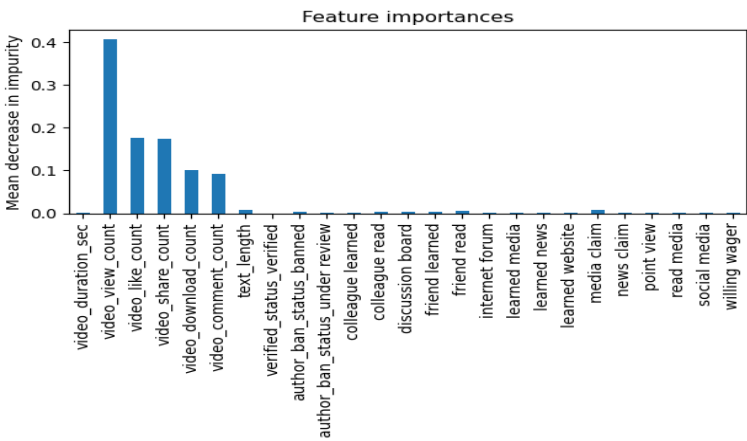

The data team built one Naive Bayes model and two tree-based classification models , Random forest and XGBOOST. The three models were used to predict on a held-out validation dataset, and final model selection was determined by the model with the best recall score. The final model was then used to score a test dataset to estimate future performance.

Details

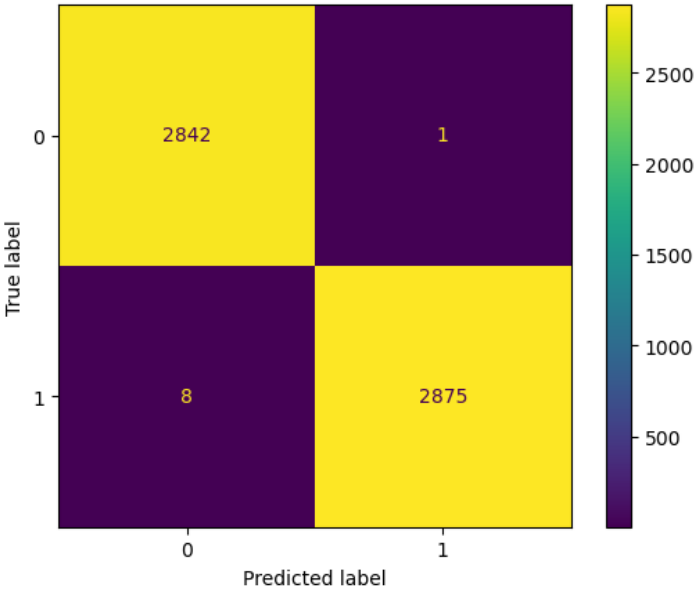

The three models architectures Naive Bayes—random forest (RF) and XGBoost—performed exceptionally well. The RF model had a better recall score (0.997) and was selected as champion.

Performance on the test holdout data yielded near perfect scores with , with only nine misclassified samples.

Subsequent analysis indicated that, as expected, the primary predictors were all related to video engagement levels, with **video view count**, **like count**, **share count**, **comment count** and **download count** accounting for nearly all predictive signal in the data. With these results, we can conclude that videos with higher user engagement levels were much more likely to be claims. In fact, no opinion video had more than 10,000 views.

Confusion matrix for the champion RF model on test holdout data shows only nine misclassified samples.

Next Steps

As noted, the model performed exceptionally well on the test holdout data. Before deploying the model, the data team recommends further evaluation using additional subsets of user data. Furthermore, the data team recommends monitoring the distributions of video engagement levels to ensure that the model remains robust to fluctuations in its most predictive features.
